A time series is a sequence of observations over a certain period. A univariate time series consists of the values taken by a single variable at periodic time instances over a period, and a multivariate time series consists of the values taken by multiple variables at the same periodic time instances over a period.

Double exponential smoothing is used when there is a trend in the time series. In that case, we use this technique, which is simply a recursive use of exponential smoothing twice. Mathematically: Double exponential smoothing expression. Here, beta is the trend smoothing factor, and it takes values between 0 and 1.

Unlike our earlier book, Time Series: Theory and Methods, re-ferred to in the text as TSTM, this one requires only a knowledge of basic calculus, matrix algebra and elementary statistics at the level (for example) of Mendenhall, Wackerly and Scheaffer (1990). It is intended for upper-level undergraduate students and beginning graduate students.

Start with the black exercises and do the harder red ones when you have time. Note that exercises marked in bold are discussed on the blackboard in the exercise session. \* Assume that the time series has a density (in terms of its finite-dimensional distribution). \*\* Replace the condition "n > p" with "n >= p".

We set  $Y_t = \epsilon_t - \theta \epsilon_{t-1}$  and then we have  $\epsilon_t = \sum_{j=0}^{\infty} \theta^j Y_{t-j}$  and expanding into  $\sum_{j=0}^{\infty} \theta^j Y_{t-j} = \sum_{j=0}^{\infty} \theta^j Y_{t-j} + \theta Y_{t-1} + \theta^2 Y_{t-2} + \dots + \theta^k Y_{t-k} + \dots$  which is equivalent to  $Y_t = \mu_0 + (1 + \theta B + \theta^2 B^2 + \dots + \theta^k B^k) \epsilon_t$  which is the definition of a MA (1) process where B is the backshift operator such that  $Y_t B^k = Y_{t-k}$ .
